## Aim

---

1. To study lattice properties via analogy of electrical oscillators.

## Introduction

normal

Most physical properties of any solid is given by its inter-molecular structure, since it forms the basis of a solid's existence. This structure often has a well-defined repeating structure known as a lattice, and this also heavily simplifies our analysis since the equations of dynamics are highly symmetric. Particularly, solids will have a state which is a minima at equilibrium. At this point, we can assume the intermolecular attraction as purely quadratic. Hence, the hamiltonian of this system is that of the Simple Harmonic Oscillator -

Where  $x$  is displacement from the minima,  $p$  and  $m$  are the momentum and mass of the atom, and  $k$  is the "stiffness constant".

## Electric Analogue

Now, consider the following LC circuit:

The hamiltonian of this system is:

$$\begin{aligned} L &\Longleftrightarrow m \\ 1/C &\Longleftrightarrow k \end{aligned}$$

Hence, this is exactly the same Hamiltonian as the previous SHO system, and hence will have the same equations of "motion". Hence, we can draw the analogy in the following way:

This analogy now allows us to easily measure the responses of an electrical system and gain knowledge about a mechanical system which is often harder to study directly.

## Monoatomic Chain

In a Monoatomic chain, all atoms are identical and hence thier masses and interatomic forces are equal. By our analogy, we can study the following LC Chain

normal

## Solving for

Assuming a charge  $q_n$  dissipating through the  $n$ th inductor, we get

An ansatz which satisfies this differeneential equation is

## Dispersion Relations

$$\ddot{q}_n = -C^{-1}q_n \implies \omega^2 = \frac{4}{LC} \sin^2 \frac{\theta}{2}$$

From the ansatz, we see

Also, the charge on capacitor  $q_{C,n}$ ,  $q_{C,n+1}$ , and the potential across capacitor  $U_{C,n}$  is  $U_{C,n+1}$  and across inductor  $U_{L,n}$  is  $U_{L,n+1}$ .

Hence,

## Plotting the Dispersion Graph

$L =$   0.5

$C =$   0.4

$C_1 =$   0.8

normal

monoatomic (generic function with 1 method)

## Analogue with the Mechanical System

### Diatomic Chain

In such a system, technically both  $\omega$  and  $\theta$  change, however, we can assume that  $\omega$  is held constant. By our analogy, we can study the following LC Chain

### Solving for

normal

Following a similar process as before,

with ansatz

## Finding the dispersion relations

---

Inserting the ansatz back into the equations, we get

Which has solutions only if determinant is 0. This condition reduces to

which has solution

## Plotting the dispersion relations

$L =$   0.5

$C =$   0.4

$C_1 =$   0.8

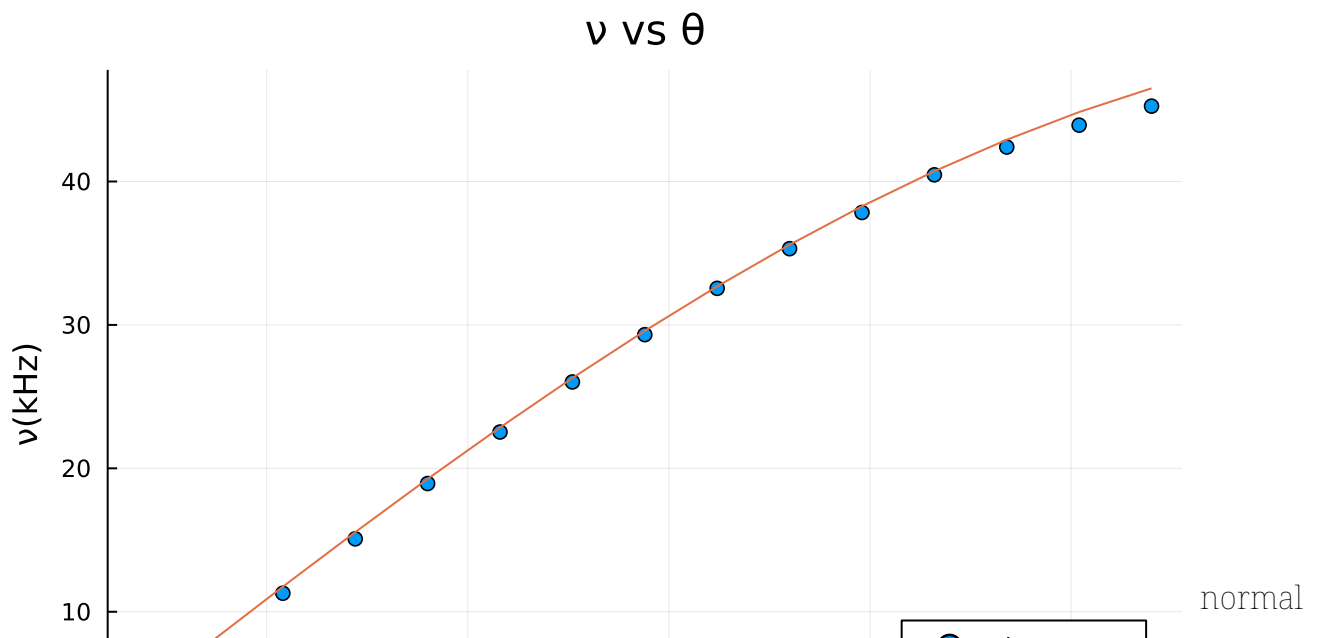

## Analogue with the Mechanical System

## Observations

From the data provided, we can plot the experimental and expected dispersion graphs.

## Monoatomic chain

# Diatomic Chain
